# CS3130 Homework 1

# Phillip Janowski (pajmc2@mail.umsl.edu) September 6, 2018

## Question 1.

(a) Find gcd(213486, 5423)213486/5243 = 39R1989

213486 = 5423 \* 39 + 1989

213486/1989 = 107R663

213486 = 1989 \* 107 + 663

213486/663 = 332R0

 $\therefore gcd(213486, 5423) = 663$ 

(b) Estimate approximately how many times faster it will be to find gcd(213486, 5423) with the help of the Euclid's algorithm compared with the algorithm based on checking consecutive integers from minm, n down to gcd(m, n) (see the algorithm #2 from the handout). You may only count the number of modulus divisions of the largest integer by different divisors.

min(213486, 5423) = 5423  $m/t \neq 0$  where m = 213486 and t = 5423 t - 1 = 5422 m - gcd(213486, 5423) = 4760 steps 4760 steps /4 steps = 1190 times faster

#### Question 2.

**2.1**) Prove the formula on which Euclid's algorithm is based:  $gcd(m, n) = gcd(n, m \mod n)$  for every pair of positive integers m and n Solution:

```
We know gcd(m, 0) = m and gcd(0, n) = n
if m = n * I + R where I is some integer and N \neq 0
then gcd(m, n) = gcd(n, R) where remainder R = m \mod n
\therefore gcd(m, n) = gcd(n, m \mod n)
```

**2.2**) 2.1-4

Given two array's A and B, length n, are added together and stored in an (n+1) length array, C

```
carried = 0
for i = n-1 down to 0
        C[i+1] = {A[i] + B[i] + carried} mod 2
        carried = {A[i] + B[i] + carried} / 2
C[0] = carried
```

#### **2.3**) 2.2-2

- (b) The loop is invariant because at the beginning of each for loop, the sorted part of the array changes in size with each iteration and only have the i-1 smallest elements
- (c) The loop only needs to run for n-1 times because the last element will already be sorted

(d) The run time of this loop is  $\theta(n^2)$ , because the inner loop runs each of its lines n times and the out loop runs its lines, including the inner loop, n times.  $\theta(n^2)$ 

## Question 3.

Modify the psuedo code on p.40 to count swaps for the bubble sort

```
i = 0
swap = 1
while swap != 0 and i < A.length
    swap = 0
    for j = A.length down to i + 1
        if A[j] < A[j-1]
        exchange A[j] < A[j-1]
        swap++
        i++</pre>
```

## Question 4.

Handwritten and Stapled to the packet

(a) Insertion Sort

R	$\mathbf{E}$	Α	L	Ι	Τ	Y	S	Н	О	W	Comparisons
R	E	Α	L	Ι	Τ	Y	S	Η	О	W	1
E	R	A	L	Ι	Τ	Y	S	Η	О	W	2
A	E	R	L	I	Τ	Y	S	Н	О	W	2

A	Ε	Н	I	L	О	R	S	Τ	W	Y	2	0
A	Ε	H	I	L	О	R	S	Τ	W	Y	1	0
A	Е	Н	Ι	L	О	R	S	Τ	W	Y	55 total	14 total

## Question 5.

(a) i = 0

(c) for i = 0 to n for j = i to n print"CS3130" 
$$= \sum_{i=0}^{n-1} \sum_{j=i}^{n-1} 1 = \sum_{i=0}^{n-1} (n-1-i+1) = n \sum_{i=0}^{n-1} 1 - \sum_{i=0}^{n-1} i = n(n-1-0+1) - \frac{(0+n-1)}{2}(n-1-0+1) = n^2 - \frac{n^2-n}{2}$$
$$= \frac{n^2+n}{2}$$

### Question 6.

2.1-3 Find v in Array A[]

This loop is invariant because at the beginning we have i = 0 at ininitialization. Maintenance, because it maintains while i < length of A or  $v \neq A[i]$ and is true before i and i + 1. And Termination, because it only terminates when v is found in A or when we run out of elements in A to check

#### Question 7.

The average performance of the linear search is  $O(\frac{n}{2})$ . The worst performance would happen from v being in the A.lengthth position of the array and the best would happen from v being in the 1st position of the array. In a set of completely random runs the average number of comparisons would eventually converge on  $\frac{n}{2}$ .
